February, 2016

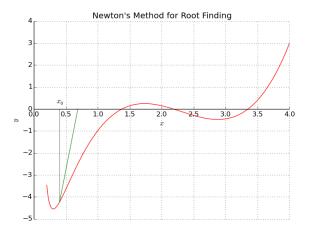

Given a differentiable function $f : \mathbf{R} \mapsto \mathbf{R}$ we want to find the instances when f(x) = 0 (not generally solvable in closed form).

Newton's Method:

- 1. Take a starting position x_0
- 2. Find where the tangent line $y = f(x_n) + (x_{n+1} x_n)f'(x_n)$ is 0 and iterate:

$$y = f(x_n) + (x_{n+1} - x_n)f'(x_n) = 0$$
$$x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$$

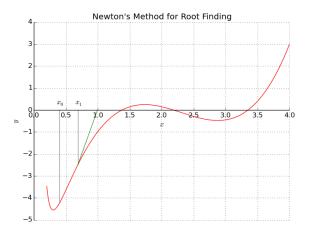

Initial
$$x_0 = 0.4$$
, $f(x) = (x - 1)(x - 3)^2 + e^{\frac{1}{3}/x} - \cos(\frac{x}{2}) - 1.5$

$$x_0 = 0.4 \quad \Delta = 0.9805$$

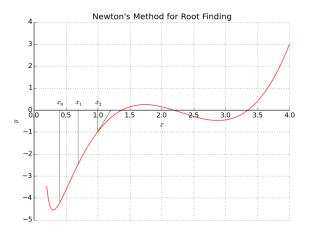

Initial
$$x_0 = 0.4$$
, $f(x) = (x - 1)(x - 3)^2 + e^{\frac{1}{3}/x} - \cos(\frac{x}{2}) - 1.5$

$$x_1 = 0.6866 \quad \Delta = 0.6938$$

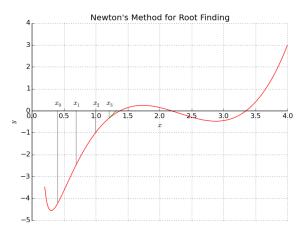

Initial
$$x_0 = 0.4$$
, $f(x) = (x - 1)(x - 3)^2 + e^{\frac{1}{3}/x} - \cos(\frac{x}{2}) - 1.5$

$$x_2 = 0.9938$$
 $\Delta = 0.3866$

Initial $x_0 = 0.4$, $f(x) = (x - 1)(x - 3)^2 + e^{\frac{1}{3}/x} - \cos(\frac{x}{2}) - 1.5$ Converges in 28 iterations.

$$x_3 = 1.2050 \quad \Delta = 0.1754$$

Optimizing Function Using Newton's Method

Instead of finding wheren f(x) = 0, how can we find where f'(x) = 0? Same method:

$$x_{n+1}=x_n-\frac{f'(x_n)}{f''(x_n)}.$$

Def: The gradient of $f: \mathbb{R}^n \mapsto \mathbb{R}$ is

$$\nabla f = \begin{bmatrix} \frac{\partial}{\partial x_1} f & \frac{\partial}{\partial x_2} f & \dots & \frac{\partial}{\partial x_n} f \end{bmatrix}.$$

Def: The Hessian of $f: \mathbb{R}^n \mapsto \mathbb{R}$ is

$$H_{f} = \begin{bmatrix} \frac{\partial^{2} f}{\partial x_{1} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{1} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{1} \partial x_{n}} \\ \frac{\partial^{2} f}{\partial x_{2} \partial x_{1}} & \ddots & \frac{\partial^{2} f}{\partial x_{2} \partial x_{n}} \\ \vdots & & \vdots \\ \frac{\partial^{2} f}{\partial x_{n} \partial x_{1}} & \frac{\partial^{2} f}{\partial x_{n} \partial x_{2}} & \cdots & \frac{\partial^{2} f}{\partial x_{n} \partial x_{n}} \end{bmatrix}$$
